The Why Tree

A Structured, Generative Technique for Externalizing and Discovering Personal Purpose

Ji Soo Yi

March 2026

White Paper
Draft for discussion and collaboration

Abstract

This white paper introduces the **Why Tree**, a structured, generative technique for discovering personal purpose. Adapted from the means-ends abstraction hierarchy in cognitive work analysis (Rasmussen, 1986; Vicente, 1999), the Why Tree works through two complementary movements: “Why Up” (asking “why?” to surface higher-level purposes from concrete experiences) and “How Down” (asking “how?” to enumerate alternative means). The process is designed to be generative rather than merely iterative: each round actively challenges the practitioner’s cognitive model, encouraging the externalization of implicit reasoning about purpose. I propose that the true outcome is not the diagram itself but the metacognitive externalization it produces. This paper situates the technique within existing purpose-finding tools—psychometric assessments, values clarification exercises, and reflective practices—arguing that the Why Tree fills a methodological gap between instruments that measure meaning without generating it and top-down exercises that presuppose self-knowledge. The paper provides instructions for the exercise and seven testable propositions for future empirical investigation.

1. Introduction

What is the purpose of my life? Few questions carry more weight, yet few prove harder to answer. Philosophers from Aristotle to Frankl (1946) have argued that a sense of purpose is fundamental to human flourishing, and a growing body of empirical research confirms it: purpose predicts longevity, resilience, and well-being across the lifespan (Steger, 2009; Hill & Turiano, 2014). The importance of the question is not in dispute. The difficulty lies in answering it. We navigate careers, relationships, and life transitions—accumulating experiences of both joy and suffering—yet the underlying purposes that drive our choices often remain inarticulate, felt rather than understood. The question persists not because people lack purpose, but because the tools for surfacing and clarifying it have been scarce.

The rapid advancement of artificial intelligence has sharpened this challenge. As AI systems grow capable of performing an expanding range of knowledge work, the skills and tasks that once defined a professional identity are increasingly automatable. Harari (2018) warns that automation may render entire occupational categories obsolete, creating what he calls a "useless class"—not because people lack ability, but because the economy no longer needs their labor. The deeper threat, he argues, is not unemployment but the loss of meaning that work once provided. Amodei (2024), writing from a more optimistic perspective, envisions AI enabling unprecedented human flourishing—but acknowledges that realizing this potential requires individuals to clarify what they actually want from life. From both perspectives, the question shifts from "What can I do?" to "What do I *want* to do, and why?" Purpose, once a matter of philosophical reflection, is becoming a strategic necessity for navigating an AI-transformed world.

This paper introduces the **Why Tree**, a structured, generative technique that addresses this gap. The Why Tree adapts the means-ends abstraction hierarchy from cognitive work analysis (Rasmussen, 1986; Vicente, 1999) for individual self-understanding. It works through two complementary movements: "Why Up" asks "Why do I do this?" to reveal higher purposes; "How Down" asks "How else might I serve this purpose?" to enumerate alternative means. I propose that the primary outcome is not the diagram itself but the **externalization of metacognition** that the process encourages—each "why?" prompts the practitioner to articulate reasoning about purpose that was previously implicit. By cycling between ascending and descending exploration, the practitioner progressively externalizes their inner model of what matters and why.

This paper is a **white paper** written at a pre-experiment stage. Its purpose is to introduce the Why Tree, situate it within relevant literature, provide practical instructions, and articulate testable propositions for future empirical investigation. No controlled study has yet been conducted. The evidence draws on classroom experience

with Work Domain Analysis and theoretical analysis. An initial classroom trial with MBA students at KAIST (Spring 2026) is speculated. The paper is intended as a foundation for collaboration with researchers who may wish to investigate the technique's claims rigorously.

2. Origins: From Systems Engineering to Self-Understanding

The Why Tree has its roots in Work Domain Analysis (WDA), a central component of Cognitive Work Analysis developed by Jens Rasmussen (1986) and later formalized by Kim Vicente (1999). WDA uses a means-ends abstraction hierarchy to model complex work domains by linking physical objects at the bottom to functional purposes at the top through layers of increasing abstraction. The key insight is that understanding *why* a system element exists is as important as understanding *what* it does or *how* it is implemented.

The author first encountered this power while teaching WDA to undergraduate students at Purdue University. Students applied means-ends decomposition to product design and reported that repeatedly asking "why?" about each feature traced decisions back to fundamental user needs, while asking "how?" generated alternative solutions. The author subsequently applied this approach professionally at Samsung Electronics, where it proved valuable for clarifying the purpose of consumer products. For example, applying the Why Tree to television revealed that its fundamental personal purpose was "passive entertainment"—a single insight that explained why efforts to make television interactive had struggled.

The transition from product analysis to personal purpose-finding occurred through a simple metaphor: *I am the product I design*. If a means-ends hierarchy could reveal the true purpose of a television, it could also reveal the purposes underlying one's own daily activities, career choices, and life decisions—with experiences, habits, and traits as "means" and values and aspirations as "ends."

3. Related Work

3.1 Meaning, Purpose, and Assessment

The study of meaning and purpose has been central to positive psychology since its founding. Seligman's (2011) PERMA model identifies Meaning as one of five pillars of well-being. Frankl's (1946) logotherapy posited that the search for meaning is the primary human motivation. Self-Determination Theory (Deci & Ryan, 2000) identifies autonomy, competence, and relatedness as basic psychological needs whose satisfaction

is essential for well-being. These frameworks provide theoretical grounding for *why* purpose matters but offer limited guidance on *how* to discover one's own purpose.

Psychometric instruments—the Meaning in Life Questionnaire (Steger et al., 2006), the Purpose in Life Test (Crumbaugh & Maholick, 1964), and Ryff's (1989) Purpose in Life subscale—can diagnose the presence or absence of meaning but do not themselves generate it. Values clarification exercises from Acceptance and Commitment Therapy (Hayes et al., 1999), including the Values Card Sort and the Bull's Eye exercise (Lundgren et al., 2012), ask individuals to select or rank from pre-existing lists—a **top-down** approach that presupposes a degree of self-knowledge many people lack. The Why Tree takes a different approach: it is **bidirectional and generative**, beginning with concrete experience and working upward toward purposes ("Why Up"), then downward to enumerate new means ("How Down").

3.2 Laddering and Adjacent Approaches

The most structurally similar predecessor is the **laddering** technique (Reynolds & Gutman, 1988), an interview method from consumer research grounded in Gutman's (1982) Means-End Chain Theory. The interviewer repeatedly asks "Why is that important to you?" to walk a subject up a chain from concrete attributes to abstract values—paralleling the Why Tree's "Why Up" movement. Related approaches include Toyota's **5 Whys** (root-cause analysis producing a single linear chain) and Sinek's (2009) **Start With Why** (which presupposes one already knows one's "Why").

The Why Tree differs from these approaches in four respects: it is **bidirectional** (alternating Why Up and How Down); produces a **network with emergent properties** (convergence and fragmentation patterns are meaningful); is **generative across time** (each revisit challenges the model, not just extends it); and incorporates a **quality check on means** through increasing complexity (Section 4.4).

3.3 Goal Systems and Metacognition

Kruglanski et al.'s (2002) goal systems theory proposes that goals are organized in hierarchical networks where lower-level goals serve higher-level ones—mapping directly onto the Why Tree's structure. Emmons and King's (1988) research on goal conflict showed that conflicting goals predict negative affect and lower well-being; the Why Tree can make such conflicts *visible* by revealing competing high-level ends that share the same means.

The Why Tree is also fundamentally a metacognitive tool. Practitioners are not merely reflecting on their lives but examining the *structure of their reasoning* about their lives. Recognizing convergence or fragmentation in one's own tree is a metacognitive insight—a pattern in one's thinking that was previously invisible. This connects the Why Tree to

research on metacognitive awareness (Flavell, 1979; Zimmerman, 2002) and structured reflection (Schon, 1983; Moon, 2004).

3.4 Positioning the Why Tree

The Why Tree is not an assessment instrument, not a values selection exercise, and not unstructured reflection. It is a **structured, bidirectional, generative technique** whose proposed primary outcome is the externalization of metacognition—articulating, through disciplined recursive questioning, the implicit reasoning about purpose that would otherwise remain unarticulated. The diagram is a useful byproduct; I hypothesize that the real contribution is the cognitive work of building it. Its closest theoretical relatives are goal systems theory and cognitive work analysis, but its practical application—as a generative tool for individual purpose-finding through metacognitive externalization—is novel. The Why Tree also has a natural complement in Le Cunff's (2025) *Tiny Experiments* approach, which advocates running small, low-cost experiments to discover what resonates. The Why Tree generates the *map* of possible means and ends through structured decomposition; Tiny Experiments provide the *testing mechanism* for validating which means actually resonate in practice. A practitioner might use the Why Tree to discover convergence on an unarticulated purpose, use How Down to generate new possibilities, and then use Tiny Experiments to test those possibilities before committing to a major life change.

4. The Why Tree Method

4.1 Preparation: Gathering Seed Material

The Why Tree begins with concrete starting points. The quality of these starting points matters; several reflection prompts have proven effective for generating honest seed material:

The Shower Question: "What do you find yourself thinking about when your mind is free—in the shower, on a walk, before sleep?" This question captures involuntary attention. Unlike questions about values or goals, which may elicit socially desirable answers, the shower question accesses what the mind naturally gravitates toward when unconstrained. Involuntary attention is a reliable signal of authentic concern. If someone consistently thinks about something entirely different from their daily work, that gap is itself a valuable datum.

The Flow Question: "When does time fly for you? When does it drag?" Csikszentmihalyi's (1990) concept of flow—the state of complete absorption in an activity—provides another indicator of alignment between activities and purpose. Activities where time flies are candidates for the bottom of the Why Tree. For

individuals with professional experience, the contrast between "time flew" and "time dragged" across their career can reveal patterns of alignment and misalignment.

The Persistence Question: "What do you keep coming back to—ideas, projects, hobbies—even when no one asks you to?" This question identifies activities sustained by intrinsic motivation rather than external rewards. These are particularly valuable starting points because they are more likely to connect to authentic purposes.

The Constraint-Free Question: "If you knew you could not fail—and had no constraints on time, money, or approval—what would you pursue?" While the Persistence Question captures what someone already does, the Constraint-Free Question liberates thinking from fear and practicality. It bypasses self-censoring to surface aspirations the practitioner may have never acted on, often producing seeds that are bolder and more revealing than those drawn from current behavior.

The Deathbed Question: "What would you most deeply regret never attempting?" This question introduces a temporal constraint that strips away short-term noise and social expectations. Like the other prompts, it yields concrete activities—seeds at the bottom of the tree, not abstract ends. Its particular value lies in the emotional weight it carries: regret is a powerful filter for separating what genuinely matters from what merely seems appealing. The answers make excellent starting points for Why Up exploration.

A note on free-time activities: while "what do you do in your free time?" can be a useful prompt, it should be used with caution. Some free-time activities—watching television, scrolling social media, drinking—function as pacifiers rather than expressions of genuine purpose. Applying the Why Tree to such activities may reveal avoidance ("I do this because I'm tired" or "because I want to stop thinking about work"), which is diagnostic but does not generate direction. The other prompts above tend to produce more generative starting points.

4.2 The Core Process

The Why Tree is built through two complementary movements, alternated generatively:

Why Up: Starting from a concrete item (an object, activity, or experience), ask "Why?" or "What is this for?" to identify the purpose it serves. Then ask "Why?" of that purpose, and continue recursively. Do this boldly—there is nothing right or wrong at this stage. For example, starting from "morning journaling": journaling → organizing my thoughts → feeling in control of my day → living intentionally. Each step moves up one level of abstraction, from concrete activity to functional purpose to abstract value.

How Down: From any node in the tree, ask "How?" or "What are other ways to achieve this?" to enumerate alternative means. For example, from "living intentionally":

morning journaling, weekly reflection, goal-setting rituals, saying no to low-priority commitments, meditation. Each step moves down one level, expanding the set of concrete means that could serve a given purpose.

The power of the technique lies in *alternating* these two movements. By going up from a concrete starting point, the practitioner discovers the purpose behind their activities. By coming back down from that purpose, they discover alternative means they had not considered. By going up again from those new means, they may discover additional purposes, some of which connect to other parts of the tree. I suggest that means are not merely servants of ends—they are *instantiations of underlying desire and inclination*. By generating new means and reprioritizing among them, the practitioner does not just find new ways to serve an existing purpose; they actively refine and deepen the ends themselves. This is what makes the process generative rather than merely iterative: each cycle does not simply repeat the previous one but challenges and extends the practitioner's cognitive model, encouraging the externalization of reasoning about purpose that was previously implicit.

Figure 1 illustrates the process with a simple example. Minjung, a hypothetical 34-year-old marketing manager enrolled in an MBA program, notices that she often finds herself rearranging colleagues' slides before presentations—not because she is asked to, but because she genuinely enjoys it. This is her seed.

Why Up. Starting from "rearranging colleagues' slides," Minjung asks: why do I enjoy this? Her answer: because she cares about making the story land for the audience. She asks why again: why does that matter? Because what she really loves is seeing the aha moments in the audience—the instant when a complex idea clicks. Two steps of Why Up have moved her from a mundane activity to an abstract purpose she had never articulated.

How Down. From "seeing the aha moments in the audience," Minjung now asks: what are other ways to create that experience? One path leads to making the data understandable—not just the narrative, but the underlying information itself. From there, she generates concrete roles she had never considered: data visualization designer, data scientist. These are career directions that were invisible from her starting point of rearranging slides, yet they serve the same discovered purpose.

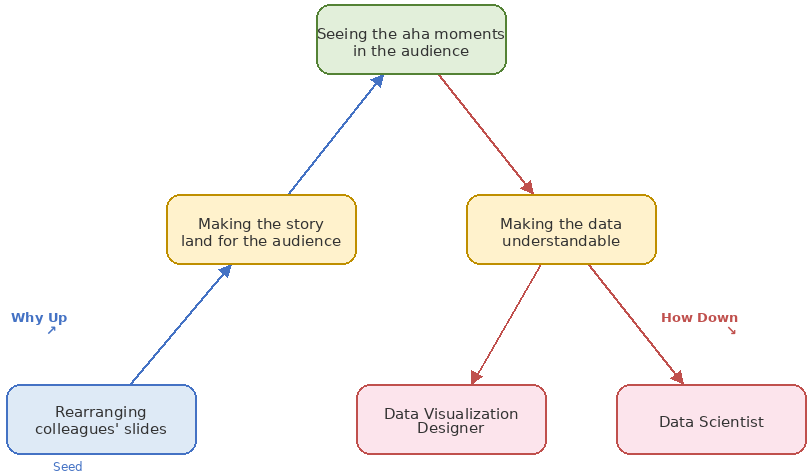

Figure 1. *Minjung's Why Tree. A single seed (blue) is traced upward through Why Up to a core purpose (green), then branched downward through How Down to generate new means and career paths (pink).*

4.3 Reading the Structure

As the Why Tree develops, its structure becomes informative in its own right:

Convergence occurs when multiple means-ends chains meet at a single node. When several different activities, habits, or interests all trace upward to the same purpose, that node represents a core value. This convergence is one of the most powerful outputs of the Why Tree—it reveals organizing principles that the practitioner may not have been able to articulate directly. It is analogous to realizing that several seemingly unrelated interests—reading, volunteering, and side projects—all serve the same deep need for creative expression.

Fragmentation occurs when the tree has multiple high-level ends with little connection between them. This suggests the practitioner is pursuing multiple purposes that may compete for the same finite resources—time, energy, and attention. Fragmentation is not inherently negative; some people thrive with diverse purposes. But it carries a cost, and the Why Tree makes that cost visible by showing the competing demands on shared means.

The network structure of the Why Tree is itself meaningful. The result is rarely a strict tree (in the computer science sense) but rather a network where a single mean can serve multiple ends, and a single end can be served by multiple means. This network structure captures the real complexity of human motivation more faithfully than a flat list of values or a simple priority ranking.

4.4 Practical Guidance and Common Pitfalls

Several lessons have emerged from classroom and personal application of the Why Tree:

How high should you go? Continue asking "Why?" until you reach an end that appears to have too many means to enumerate—for example, "happiness." At that point, the concept is likely too broad to be practically useful. The most informative nodes tend to sit one or two levels below such universal ends. The number of means below a given end defines the scope of your thinking, and it is your choice how broad that scope should be. Sometimes a broad scope is desirable; sometimes a narrower focus is more useful.

How deep should you go? Continue asking "How?" until you reach a level of detail you care about—specific daily habits, commitments, or concrete actions you could take tomorrow.

Push past shallow chains. Some practitioners struggle to "Why Up" enough, producing chains like "exercise → staying healthy" and stopping there. There is always more to discover. Why does staying healthy matter to you? What does health enable that you truly care about? Something may be blocking further exploration—perhaps the answer is uncomfortable or unfamiliar—but the most valuable insights often lie beyond the point of initial resistance.

Break solution fixation. One of the most powerful benefits of the Why Tree is its ability to break fixation on a particular solution. When someone believes they need a "better job," the Why Tree may reveal that the actual end is "creative autonomy"—and once that end is visible, entirely different means become apparent: side projects, internal role changes, or freelance work that would satisfy the same purpose without a full career switch.

Check for increasing complexity. Csikszentmihalyi (1993) argued in *The Evolving Self* that genuine growth involves increasing complexity—activities that simultaneously *differentiate* (becoming more unique and specialized) and *integrate* (connecting to larger systems of meaning). This principle provides a valuable quality check for the means in a Why Tree. Consider: the same starting activity can appear at the bottom of the tree, but its relationship to purpose differs dramatically depending on whether it involves increasing complexity. "Watching television" as passive consumption is a low-complexity pacifier with a shallow Why Up chain ("I watch → I relax"). But "becoming an influential critic of television" involves deepening knowledge, developing a unique analytical voice, and building an audience—increasing complexity serving the same apparent starting point, with a far richer set of upward connections. Similarly, casual gaming is a pacifier, but professional esports involves progressive skill development, strategic depth, and community engagement. After building the initial tree, examine

each mean and ask: "Is this activity growing in complexity, or has it plateaued?" Means that are increasing in complexity are more likely to be genuine expressions of purpose. Means that have plateaued may be pacifiers or habits that have outlived their usefulness.

Plan for generative revisiting. The Why Tree is not a one-time exercise. A single round should take approximately 30 minutes, but a complete tree cannot be built in one sitting. The technique requires multiple rounds over time, and each round is generative—it does not merely repeat but actively challenges the practitioner's current model. As new means are explored, existing ends may be refined, and as ends are clarified, entirely new means may emerge. The tree is a living document, not a finished product.

5. Discussion

Limitations. The Why Tree has not yet been empirically validated. The evidence presented here is based on classroom experience with product design applications and theoretical analysis. The technique's effectiveness likely depends on the quality of starting points and the practitioner's willingness to push beyond comfortable answers. In group settings, the prospect of sharing may lead to self-censoring; facilitators should keep the core exercise private.

Applications. The Why Tree holds promise in education (students navigating career decisions), coaching (complementing values clarification techniques), and organizational development (diagnosing misalignment between work activities and personal purpose). Empirical studies with students in their mid-thirties pursuing career advancement will provide initial data on feasibility and perceived value, using a pre/post study design in which students write about their purpose before and after the exercise.

Beyond initial discovery. The Why Tree is not only a tool for first-time purpose discovery but also for **purpose management over time**. As new projects, roles, and experiences enter one's life, they can be connected to the existing tree, providing a framework for evaluating whether new activities serve existing ends or introduce competing purposes. The technique can also diagnose misalignment: when daily work activities do not connect upward to one's core purposes, the gap becomes visible in the tree's structure—experienced not as diffuse dissatisfaction but as a legible mismatch between means and ends. In this sense, the Why Tree functions not just as a reflective exercise but as an ongoing strategic framework for a purposeful life.

6. Propositions for Empirical Investigation

The Why Tree rests on several theoretical claims that, if validated, would contribute not only to practice but to our understanding of how self-knowledge is constructed. This section articulates them as testable propositions—a research agenda for future empirical work.

Proposition 1: Externalization as mechanism. The Why Tree's primary contribution is hypothesized to be not the diagram but the metacognitive externalization the process elicits—the articulation of previously implicit reasoning about why one's activities matter. If correct, outcome quality should depend on the depth of the articulation process, not the visual completeness of the diagram.

Proposition 2: Means reshape ends. A standard hierarchical model assumes ends are fixed and means interchangeable. The Why Tree suggests a more dynamic relationship: means are instantiations of underlying desire. Generating new means through How Down may actively refine or transform the practitioner's understanding of their ends—a testable prediction that distinguishes the Why Tree from static goal-hierarchy models.

Proposition 3: Convergence reveals core values. When multiple chains converge on a single node, the Why Tree interprets this as evidence of a core value. However, convergence could alternatively reflect post-hoc rationalization. Empirical work should examine whether convergence predicts behavioral coherence and well-being, and whether surprising convergence differs in predictive power from expected convergence.

Proposition 4: Generative, not merely iterative. If each round generatively challenges the cognitive model, successive rounds should produce structural reorganizations and reinterpretations—not just additions. Longitudinal tracking can test whether later rounds show genuine model revision or merely incremental elaboration.

Proposition 5: Increasing complexity as quality check. Means exhibiting increasing complexity (Csikszentmihalyi, 1993)—simultaneous differentiation and integration—should be more likely to express genuine purpose, while plateaued means may be pacifiers. Practitioners with more high-complexity means should report greater alignment and higher meaning-in-life scores.

Proposition 6: Complementarity with experimental validation. The Why Tree generates the *map* through structured decomposition; Le Cunff's (2025) Tiny Experiments provide the *testing mechanism* for validating which means resonate in practice. Whether this combined cycle produces greater purpose clarity than either approach alone is worth investigating.

Proposition 7: Seed question validation. The five seed prompts proposed in Section 4.1 (Shower, Flow, Persistence, Constraint-Free, and Deathbed) each target a

distinct psychological mechanism—involuntary attention, absorption, intrinsic motivation, aspiration freed from fear, and regret as authenticity filter. Whether all five are necessary, whether some produce overlapping seeds, and whether certain prompts are more generative for particular populations are open empirical questions. Future studies should evaluate the discriminant validity and relative yield of each prompt.

These propositions are offered in the spirit of a white paper: clearly articulated hypotheses grounded in theory and personal experience, awaiting empirical test. This paper invites researchers and practitioners to join in that investigation.
